AUTHOR: Kalivoda, Aleš, Engineer

TITLE: Determination of the Coefficient of Activity of Carbon  
in Alloy Ferrite

PERIODICAL: Hutnické listy, 1960, No.9, pp.687-689

TEXT: For measuring the carbon activity the author used a method proposed by Hillert (Ref.6), according to whom the carbon activity in cementite and ferrite in the equilibrium state can be expressed by means of the equation

$$\frac{a_c \text{ pure cementite} + \alpha}{a_c} = 0.0553 \cdot \exp. 6900/RT$$

and the ratio of the activity of the carbon in a mixture of the alloy cementite and ferrite to that of a mixture in pure cementite can be calculated by means of the equation

$$\frac{\frac{a_c \text{ cementite} + \alpha}{a_c}}{\frac{a_c \text{ pure cementite} + \alpha}{a_c}} = -y(4F - 3) \quad (1)$$

Determination of the Coefficient of Activity of Carbon in Alloy Ferrite

where  $y$  is the content of the alloying element in the ferrite (gram molecule weight fraction),  $F$  is the ratio of the gram molecule weights of the alloying elements in the two phases. This equation was derived by Hillert on the assumption that a ternary alloy forms a diluted solution and that for a second component (the alloying element in the given case), the Henry law applies. For the experiments four steels with a carbon content of about 0.4% were chosen which were alloyed each time with about 2% of one of the following elements; manganese, silicon, chromium and nickel, whilst the other elements were contained in as small a quantity as practicable (Table 1). It was found that manganese, and particularly chromium, reduce considerably the activity of carbon as compared to a pure Fe-C alloy, i.e. these elements reduce the quantity of "free" carbon which is capable of interacting. However, nickel does not influence the activity of the carbon as compared to a Fe-C alloy and its influence on the carbide reaction is negligible. For the given content, silicon increases the

TITLE: Changes in mechanical properties of spirally welded pipes due to cold deformations

SOURCE: Hutnik, no. 3, 1965, 119-122

TOPIC TAGS: material deformation, solid mechanical property, pipe, plastic deformation, steel, weldability

ABSTRACT: Experiments showed that the plastic deformation in pipe production increases the strength of the material, but at the same time the elongation is reduced by about 4%, and the notch strength is reduced by 25%, while the brittleness increases. Welding properties were not influenced. Two kinds of steel were used in the experiments. First containing: 0.26% C, 0.44% Mn, 0.04% P and 0.052% S; the second: 0.13% C, 0.48% Mn, 0.3% Si, 0.018% P, and 0.024% S. Orig. art. has: 5 figures and 1 table.

AUTHOR: Kalivoda, Aleš, Engineer

TITLE: Retained Austenite

PERIODICAL: Hutnické listy, 1961, No.2, pp.135-138

TEXT: According to the results of Castleman, Averbach and Cohan (Ref.1) and Bailey and Harris (Ref.2), retained austenite has an unfavourable influence on quenched and even on tempered specimens; its decomposition products lower some of the mechanical properties, particularly the notch impact strength. In view of the importance of this problem, the author has studied retained austenite by means of a magnetometer for the case of tempering of steels tempered up to 400°C, i.e. in the range of the so-called low temperature temper brittleness. The aim was: 1) to verify the quantity of retained austenite in steel of a given type as a function of the austenitization temperature; 2) to determine the quantity of retained austenite as a function of the conditions of cooling during quenching; 3) to study the decomposition of the retained austenite during tempering as a function of the hardening conditions; 4) to evaluate the factors affecting the stabilization of retained austenite. The retained austenite was evaluated by apparatus of the same type as Card 1/6

Retained Austenite

Z/034/61/000/002/003/006  
E073/E535

that described by Shteynberg and Zyuzin (Ref.3), i.e. a magnetometer in which, after initial demagnetization of the specimen, the residual magnetic phase is determined on the basis of the e.m.f. generated by the specimen after magnetization. For measuring the retained austenite, Cr-Ni-Mo (ČSN 16341) constructional steels were chosen, which were smelted in 50 kg high frequency furnaces with basic linings. Cast ingots were forged into rods of 20 and 8 mm diameter, respectively; the rods of 8 mm diameter were cut into thirteen 70 mm long pieces and quenched by various methods as enumerated in Table 1. For hardening, the rods were heated to the desired temperature with an accuracy of  $\pm 3^{\circ}\text{C}$ . Following that, they were cooled, either suspended in air or by immersion into an appropriate bath. After hardening, two 3 x 30 mm specimens were prepared from each rod for determining the retained austenite, which was measured twice for each specimen, i.e. four times for each alternative heat treatment. Then, the specimens were tempered gradually at 50, 80 and 100°C in a water bath, at 150 and 200°C in an oil bath and at 250, 300, 350 and 400°C in an air furnace (inside sealed silicon tubes to prevent decarburization).

Card 2/6

Retained Austenite

Z/034/61/000/002/003/006  
E073/E535

The tempering time was four hours. The quantity of retained austenite was determined at 20°C after each tempering. The influence of the hardening temperature, of the speed of quenching, of the temperature of the quenching bath on the quantity of the retained austenite and the nature of the decrease in the quantity of retained austenite for all the tested variants of the heat treatment are plotted in Fig.2, which gives the quantity of retained austenite, %, as a function of the tempering temperature, °C; the numbering of the curves corresponds to that of Table 1. On the basis of the obtained results, the following conclusions are arrived at:

1. With decreasing cooling speed a greater quantity of retained austenite will form. The retained austenite can be entirely eliminated by intensive quenching followed directly by cooling in liquid nitrogen.
2. During tempering the retained austenite is stable up to 200°C; decomposition occurs to a maximum extent in the range of 250 and 300°C and exceptionally at higher temperatures. Retained austenite which has been stabilized by quenching in an oil bath

Card 3/6

Retained Austenite

Z/034/61/000/002/003/006  
E073/E535

✓

of 200°C will not decompose even at 400°C.

3. An increase in the quenching temperature during quenching in water, in air and in a bath at a temperature of 100°C has no effect on the quantity of retained austenite; quenching in a 200°C oil bath results in a pronounced increase of the quantity of retained austenite.

4. The experimental results prove that martensite occurs as a result of nucleation of the defects of the austenite lattice. Defects in the austenite lattice, which are advantageous from the point of view of martensite nucleation, occur either during quenching or during slow cooling. If, during slow cooling, suitable new defects do not arise, the defects that are present during equilibrium austenitization will manifest themselves. There are 2 figures, 1 table and 12 references: all non-Czech.

TITLE: Production of steel according to DIN 17100

SOURCE: Hutnicke listy, no. 2, 1966, 123-127

TOPIC TAGS: steel industry, metallurgic process

ABSTRACT: The author investigated the problem of producing steel in accordance with DIN 17100 at the Nova Hut Works. The basic process is conducted according to CSN Class 11; details of adjustments to this process are described. Angle iron and bars were successfully produced. Czechoslovak standard construction steels are compared to British standard steels, and the improvements that would be necessary to equal British Standards are discussed. TITLE: Contribution to study of splitting of plasma shock waves in accelerating  
tube 44, 55 44, 55 44, 55  
SOURCE: Chekhoslovatskiy fizicheskiy zhurnal, v. 15, no. 7, 1965, 534-535, and  
insert on p. 540a 21, 44, 55  
TOPIC TAGS: plasma shock wave, shock wave structure, plasmoid acceleration, plasma  
magnetic field 21, 44, 55  
ABSTRACT: The authors have observed that when a shock wave is accelerated between straight conductors in a plasma, the plasmoids are emitted with different velocities, thus indicating a splitting of the shock wave. Since this phenomenon is similar to that occurring in a Marshall jet, the authors attempt to attribute it to a similarity in the configuration of the internal magnetic field in both cases. Just as in the Marshall tube the magnetic field at the middle conductor is larger than at the jacket, so is the magnetic field inside straight conductors much larger at the two conductors than in the middle between them. The authors therefore express the opinion that one of the main causes of the splitting of the shock wave

in a tube of straight conductors and of the plasmoid and the Marshall jet is the great nonuniformity of the internal magnetic field. "This work was carried out at the instigation of Assistant Professor J. Kracik to whom the authors are grateful." Orig. art. has: 2 figures.

TITLE: Influence of the stack gases of the aluminum plant at Ziar upon Hron upon the bird population in its neighborhood

SOURCE: Biologia, no. 2, 1965, 109-121

TOPIC TAGS: air pollution, industrial waste, industrial plant, aluminum, plant injury, biologic reproduction

ABSTRACT: It seems that the population of birds is influenced mainly by the presence of fluorine. Because of the systematic fluorine discharge, trees, mainly evergreens and fruit trees, are affected; in the second step all trees, even deciduous ones, suffer. As a result of these changes, facilities for nest building by the birds are reduced. Some kinds of birds find nesting possibilities at the border areas; the areas will change in the same way as the destruction of further vegetation bases will proceed. Orig. art. has: 4 tables. TITLE: Controlled studies of comparative treatment of scarlet fever with various penicillin preparations

SOURCE: Medicinski glasnik, no. 8-9, 1965, 191-194

TOPIC TAGS: penicillin, drug effect, bacterial disease

ABSTRACT: Three groups of 50 patients each, all with scarlet fever, were treated with either an oral preparation of penicillin, an injectable penicillin, or long-acting benzathine penicillin: while all 3 preparations were about equally effective on an immediate basis, the third was best in preventing reinfection or recurrence (46% versus 30% versus 6% recurrence).
